Docker image for the class → [fpisk/cttp](#)

The screenshot shows a Docker repository page for the image `fpisk/cttp`. The page includes a search bar, navigation links for Dashboard, Explore, Organizations, Create, and a user icon for `fpisk`. Below the header, it displays the repository name `fpisk/cttp` with a star icon, and a note that it was last pushed 2 days ago. A navigation bar at the top of the main content area includes links for Page Info, Tags, Collaborations, Webhooks, and Settings. The main content area contains two sections: 'Short Description' and 'Full Description'. The 'Short Description' section states: 'Computational Techniques for Thermochemical Propulsion. Federico Piscaglia, Politecnico di Milano'. The 'Full Description' section provides a detailed explanation of the Docker image, mentioning Ubuntu-18.04, OpenFOAM-6, and a class on CFD simulation of turbulent multiphase reactive flows. It also credits Prof. Federico Piscaglia from the Dept. of Aerospace Science and Technology, Politecnico di Milano. To the right of the main content, there is a sidebar with a 'Docker Pull Command' field containing `docker pull fpisk/cttp`, and an 'Owner' section showing the profile of `fpisk`.

You can reproduce the steps of this presentation by OpenFOAM-7.

tutorial

geometry

bkg mesh

castellated

snap

layering

quality

parallel

conclusions

By default OpenFOAM defines a mesh of arbitrary polyhedral cells in 3-D, bounded by arbitrary polygonal faces, i.e. the cells can have an unlimited number of faces where, for each face, there is no limit on the number of edges nor any restriction on its alignment.

A mesh with this general structure is known as a `polyMesh`; this type of mesh offers great freedom in mesh generation and manipulation in particular when the geometry of the domain is complex or changes over time.

conclusions

The constant directory contains the description of a finite volume mesh in a subdirectory polyMesh, whose definition is based around faces:

- internal faces connect 2 cells and
- boundary faces address a cell and a boundary patch.

Each face is therefore assigned an ‘owner’ cell and ‘neighbour’ cell so that the connectivity across a given face can simply be described by the owner and neighbour cell labels. In the case of boundaries, the connected cell is the owner and the neighbour is assigned the label ‘-1’. With this in mind, the I/O specification consists of the following files:

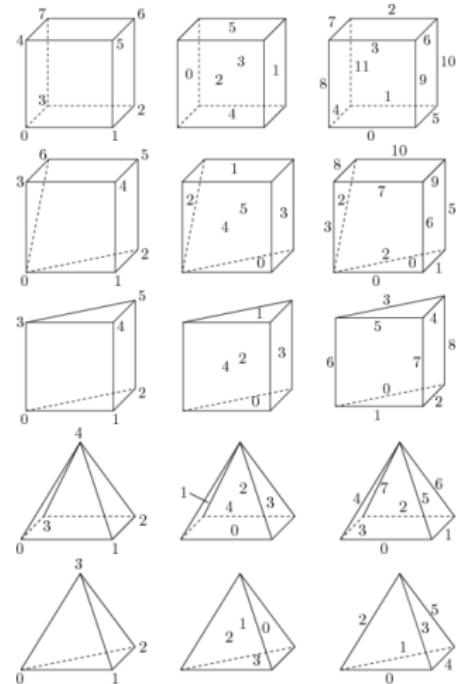

Cell shapes

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

In addition to topological data, the finite volume mesh incorporates information about its geometric entities:

- volume of CVs,
- the area of faces
- centroids of elements and faces
- the alignment of faces with the vectors joining the centroids of the owner and neighbor elements, etc.

Depending on the cell shape, the geometrical features of the cell entities are calculated. In OpenFOAM, cells are treated as polyhedra.

Mesh description

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

layering

quality

parallel

conclusions

OpenFOAM is designed as a code for 3-dimensional space and defines all meshes as such.

- However, 1- and 2- dimensional and axi-symmetric problems can be simulated in OpenFOAM by generating a mesh in 3 dimensions and applying special boundary conditions on any patch in the plane(s) normal to the direction(s) of interest.
- More specifically, 1- and 2- dimensional problems use the empty patch type and axi-symmetric problems use the wedge type.

Generating a mesh in OpenFOAM

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

layering

quality

parallel

conclusions

Two different automatic mesh generators are available in OpenFOAM®:

- the `blockMesh` utility for generating simple meshes of blocks of hexahedral cells;
- the `snappyHexMesh` utility for generating complex meshes of hexahedral and split-hexahedral cells automatically from triangulated surface geometries in `STL` or `Obj` format.

snappyHexMesh

Prerequisites to run snappyHexMesh

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

layering

quality

parallel

conclusions

- a **CAD software** to edit/repair the input geometry; snappyHexMesh works with CAD files in stereolithography format (STL), that are also used for 3D printing. Free software to manipulate STL files are freeCAD or MESHMIXER by Autodesk.

- System requirements:

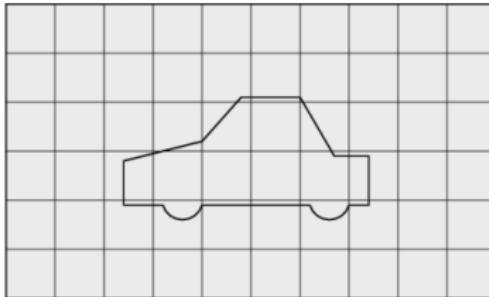

- OpenFOAM installed (in this presentation version 7 is used);
- a good amount of memory: snappyHexMesh makes use a significant amount of RAM memory during its operation (about 4 GB of RAM per million of cell volumes generated). If you want to generate large grids, consider to use dedicated resources (computational nodes);
- Message Passing Interface (MPI) installed on the machine for parallel computation;
- ptscotch: software package and libraries for sequential and parallel graph partitioning, static mapping and clustering, sequential mesh and hypergraph partitioning, and sequential and parallel sparse matrix block ordering;

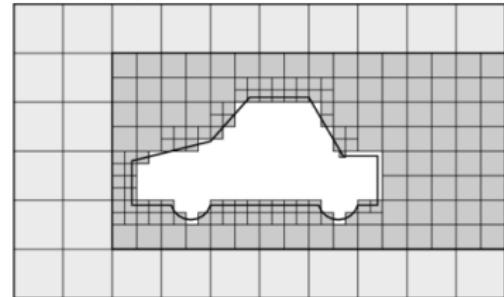

Mesh generation with snappyHexMesh

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

layering

quality

parallel

conclusions

snappyHexMesh generates a mesh by refining background cells,

- removing unwanted cells (e.g. outside the geometry) - castellated mesh
- smoothing boundaries and snapping vertices to geometry surfaces
- and inserting layers of cells

Configuration and settings are included in the [system/snappyHexMesh-Dict](#) file, that contains:

- 3 switches to control individual meshing processes
- 3 subdictionaries, one for each meshing process, e.g. snapControls
- a geometry subdictionary for the surface geometry used in the meshing
- a meshQualityControls subdictionary for the quality criteria

Input geometry (surface mesh)

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

layering

geometry { ... }  
  
castellatedMeshControls { ... }  
  
snapControls { ... }  
  
addLayersControls { ... }  
  
meshQualityControls { ... }
```

The STereo Lithography (STL) file format

STL stands for **STereo Lithography** file format;

- it is a standard, open format used in many fields (e.g. 3D printers)
- can be exported by nearly any CAD/meshing application
- Surfaces are described using **triangulation**, rather than analytical functions (like IGES or STEP).
- Files can be written in **binary** or **ASCII** (i.e. plain-text) format.
- Different surfaces in the same file are known as **SOLIDS**

STL file format: structure

Input geometry: requested features

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

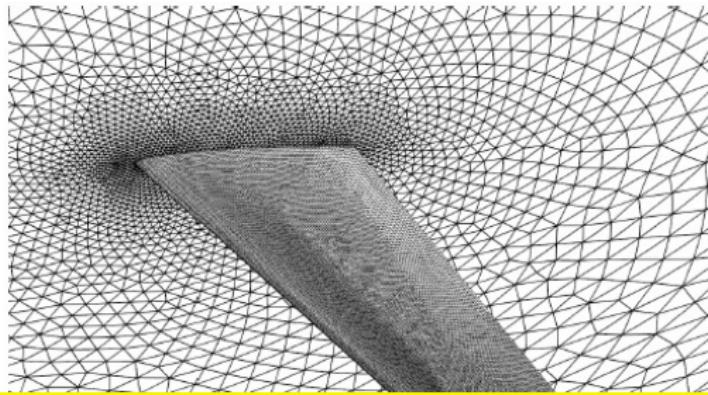

- The surface must be **closed**:
 - it may extend its open ends beyond the boundaries of the base mesh;
 - gaps in the surface must be possibly avoided
- the surface must have **no degenerated triangles**: use `surfaceCheck` utility
- face normals must be consistent: a sudden change in surface normal is seen as a feature edge;
- STL solids will become final mesh patches
- open surfaces can be used to specify `faceZones`, extra refinement regions

Input geometry: requested features

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

- The surface
 - it may
 - gaps in
- the surface must have **no degenerated triangles**: use `surfaceCheck` utility
- face normals must be consistent: a sudden change in surface normal is seen as a feature edge;
- STL solids will become final mesh patches
- open surfaces can be used to specify `faceZones`, extra refinement regions

Using **clean, smooth surfaces** can let you save a lot of time later on!

mesh;

The surfaceCheck utility

intro
blockMesh
snappy

tutorial
geometry
bkg mesh
castellated

snap
layering
quality

parallel

conclusions

- Surface files must be in <caseFolder>/constant/triSurface
- Similarly to checkMesh, it is possible to assess the quality of a triangulated surface:

surfaceCheck

- Pay attention to the bounding box: lengths are in meters in OpenFOAM!

```
Reading surface from "ahmedBody.stl" ...
```

```
Statistics:
```

```
Triangles      : 94186
Vertices       : 47440
Bounding Box  : (9.43285e-7 0.2 -195.251) (1044 194.913 144.099)
```

- If necessary, you can use surfaceTransformPoints to scale down the geometry:

```
surfaceTransformPoints -scale "(1e-3 1e-3 1e-3)" <inFile> <outFile>
```

The surfaceConvert utility

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

- the `surfaceConvert` utility converts surfaces from one data format to another
- available formats are:

File ext	Format
.ftr	OpenFOAM triangulated forma
.stl	Stereolithography (STL) ASCII
.stlb	Stereolithography (STL) binary
.obj	Wavefront object (OBJ)
.off	3D Object File Format (OFF)
.vtk	Visualization Toolkit (VTK)
.tri	Triangle format
.ac	Inivis AC3D
.smesh	TetGen surface mesh format
.dx	OpenDX format

Note: the VTK format includes a “region” field that can be used to color patches. To convert surface grids into VTK, type:

```
surfaceConvert <fileName>.obj <outFile>.vtk
```

This can be technically done also with STL file formats, if patches are explicitly labelled as “solid”.

Note: the #include directive in dictionaries

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

- The #include syntax includes one input file from another
- The included file can be specified by local or full path, e.g.

```
#include "surfaceFeatureExtractDictDefaults"
```

or

```
#include "$FOAM_CASE/system/surfaceFeatureExtractDictDefaults"
```

- The code interprets the \$FOAM_CASE environment variable as the case and system environment variables, e.g. \$WM_PROJECT_DIR

Example of Application: the Ahmed body

conclusions

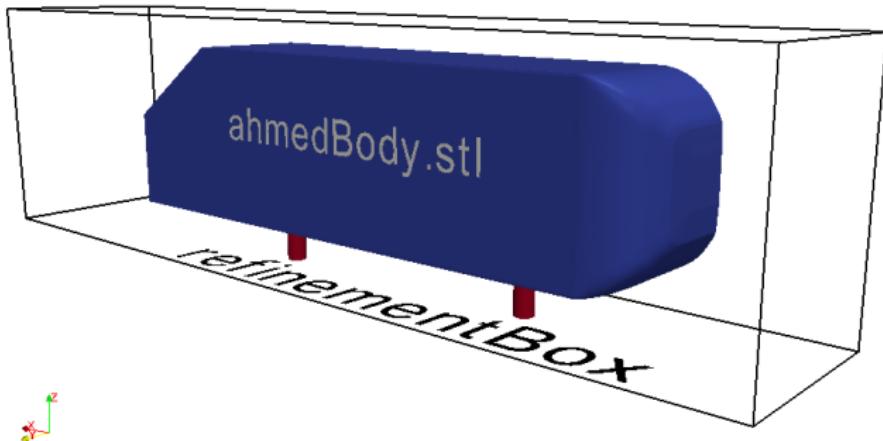

1. Define the geometry

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

- Each STL solid will be a patch in the final mesh (ASCII format required!)
- Solid name in the file can be redefined
- Define also refinement boxes, etc...

Explicit feature extraction (optional)

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

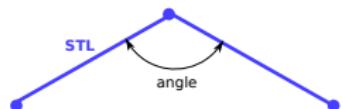

Explicit feature extraction (optional):

- you can use ParaView to select angle (filter: Feature Edges)
- you can use ParaView to load edgeMesh.obj
- use the surfaceFeatureExtract utility

```
ahmedBody.stl
{
    extractionMethod      extractFromSurface;

    extractFromSurfaceCoeffs
    {
        includedAngle      150;
        geometricTestOnly  yes;
    }
    // for post-processing
    writeObj              yes;
}
```

2. Generate the background mesh

intro

blockMesh

snappy

tutorial

geometry

bkg mesh

castellated

snap

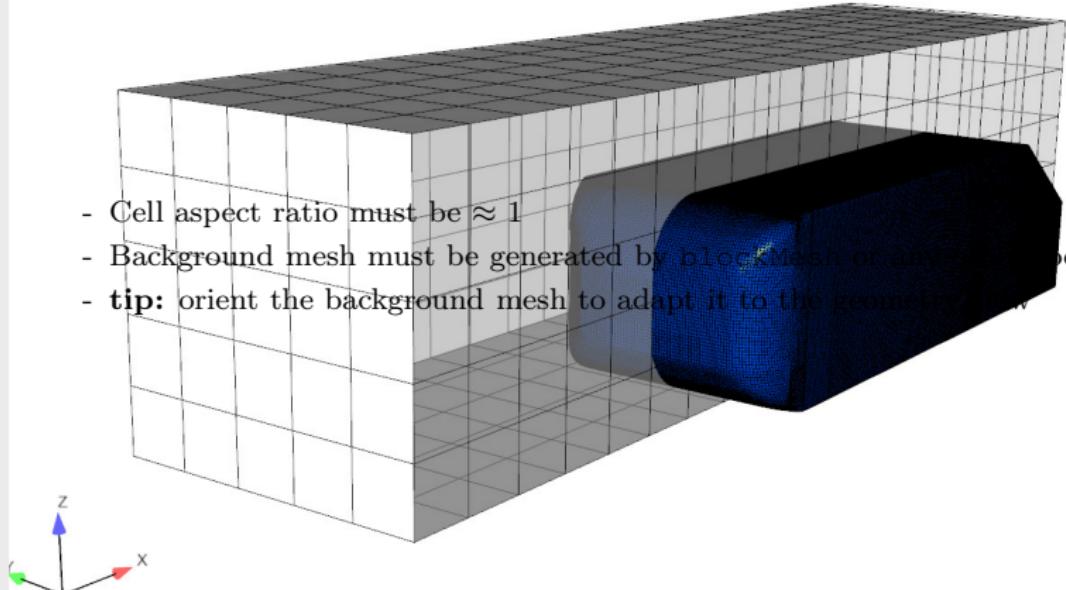

layering

quality

parallel

conclusions

- Cell aspect ratio must be ≈ 1
- Background mesh must be generated by `blockMesh` or `snappyHexMesh`
- **tip:** orient the background mesh to adapt it to the geometry

Generate the background mesh

quality
parallel
conclusions

Note: external patches (generated by blockMesh should have descriptive names and correct types!

```
boundary
{
    frontAndBack
    {
        type patch;
        faces
        (
            (blk0 2)
            (blk0 3)
        );
    }

    inlet { ... }
    outlet { ... }

    lowerWall
    {
        type wall;
        faces
        (
            (blk0 4)
        );
    }

    upperWall { ... }
};
```

3. Castellated Mesh Generation

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

Max Number of Cells Per Processor (maxLocalCells): specifies the maximum number of cells per processor during the refinement phase. If local number of cells is greater than Max Number of Cells Per Processor (maxLocalCells) on any processor the algorithm switches from refinement followed by balancing (current method) to balancing before refinement (weighted).

Global Max Number of Cells (maxGlobalCells): specifies the maximum overall number of cells during the refinement phase. Refinement process will terminated immediately when the overall cells during refinement exceed this number. In this case it may be that the refinement level might not complete. (for example some region refinements are not carried out) → do not exceed 15M cells every 8 cores, unless you have lot of RAM memory!

Cell Limit for Refinement Termination (minRefinementCells): specifies the minimum number of cells during the refinement phase. For instance the surface refinement algorithm might spend lots of iterations refining just a some cells. This setting will cause refinement to stop if cells to be refined are less than specified value Note: at least one iteration will be done, unless the number of cells to refine is 0.

Castellated Mesh Generation

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

Max Processor Load Imbalance (`maxLoadUnbalance`): specifies the maximum unbalance for processors in parallel meshing process. A value of 0 forces to balance always.

Buffer Cell Count between Refinement Levels (`nCellsBetweenLevels`): specifies the number of cell layers between different levels of refinement; 1 means that if required only a single intermediate layer is added to match the refinement difference. Larger values like 5, will add more intermediate cell layers to gradually cover the refinement difference but greatly effect the mesh size.

Castellated Mesh Generation

intro

        maxBoundarySkewness 25;
        maxInternalSkewness 8;
    }
}
```

- If a constraint is not fulfilled, the action (snap, layer addition) is undone and another trial is made with a relaxed displacement
- Too loose constraints may result in a poor mesh
- Too tight constraint will result in a long process and, possibly, in no result (esp. layers)
- If the layer loop exits because nLayerIter has been reached, additional nRelaxedIter with looser quality constraints are performed

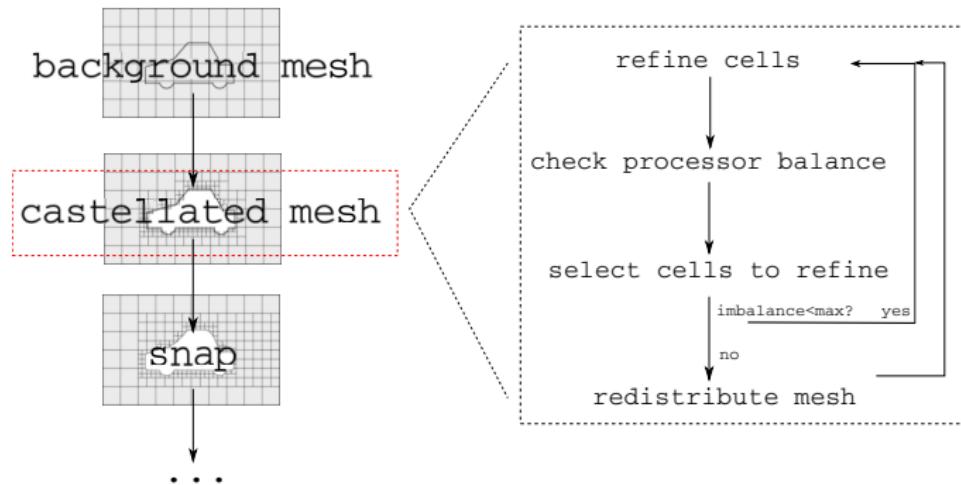

snappyHexMesh on parallel architectures

intro
blockMesh

snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality

parallel
conclusions

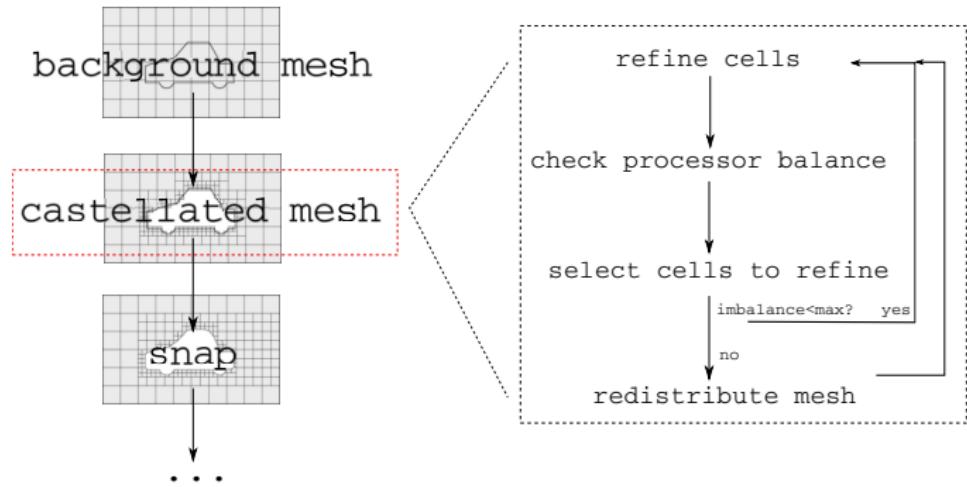

- snappyHexMesh can run on any number of processors, thus achieving **parallel mesh generation**
- Exploits **ptscotch** parallel decomposition library
- Mesh needs to be redistributed so long as cells are refined, to maintain a balanced decomposition

snappyHexMesh on parallel architectures

intro
blockMesh
snappy
tutorial
geometry
bkg mesh
castellated
snap
layering
quality
parallel
conclusions

- Mesh redistribution is very time-consuming: a tradeoff must be sought
- Inter-processor communication is required also during snap and layer addition

conclusions

snappyHexMesh is a tool for **automatic** mesh generation.

- it is **not** a CAD tool: supplied geometry must be already ‘clean’
- algorithm parameters must be supplied by the user (for some of them, default values are OK)
- Perfect for parametric/optimization studies

snappyHexMesh works in parallel

- very convenient for large cases (up to 100M cells)
- works on any cluster with MPI architecture
- mesh redistribution is an actual bottleneck
- drawback: non-negligible memory consumption

The resulting generated mesh is hexa-dominant, not-oriented; it favors a very good performance in combination with the numerical solvers of OpenFOAM.

snappyHexMesh: pro and cons

parallel

conclusions

- What are the main advantages of snappyHexMesh?

- It is an open-source tool capable of dealing with complex geometries;
- it generates hexa-dominant mesh;
- it works in parallel and favors fast generation of large grids;
- it is very easy to configure in automatic workflows, to carry out parametric studies/optimization workchains;
- it is a great tool to for fast generation of complex geometries.

- Are there any drawbacks?

- a graphical interface is missing (though some alternatives exist)
- it is not the best option to simulate wall-bounded flows where oriented grids are needed.
